

Collaborative 43 · Transforming fitness-certificate review: from mass checking to automated inconsistency detection

Internal note based on the explanatory email shared on behalf of María José Mancebo.

1. Context

Within occupational health and prevention, reviewing fitness certificates is not only about reading fit or unfit. It also requires checking identity, role, work center and the consistency between applied protocols and the risks defined for each function.

The issue grows when that review must be done one certificate at a time across many people, centers and job profiles.

2. What the current model breaks

The current setup consumes high-value technical time in repetitive checking, raises the risk of human error and makes the process difficult to scale consistently.

It also shifts focus away from preventive judgment and toward mass routine verification.

3. The proposed improvement

The proposal is to implement an automated prior validation that checks core data, role-center alignment and consistency between applied protocols and the risks defined for that function.

The system would then flag inconsistencies, deviations or doubtful cases and reserve human review only for the certificates that genuinely require intervention.

Executive conclusion: the real value lies not in reviewing everything in the same way, but in automatically identifying where inconsistency sits so technical attention can focus where it matters.
